

MYNTRA RETURNS REDUCTION — DATA-DRIVEN CASE STUDY

Product Recommendation

Launch a Fit Confidence layer first — personalized size recommendation + garment-measurement size charts + review-derived fit signals

A Strategic Conclusion

Treat AR try-on as a targeted second-stage test, not the first fix for sizing uncertainty because if incorrect size selection is the primary problem, correcting size information or recommendations may be less expensive and easier to measure than developing a complex AR system right away.

Signal	What the public evidence says	Product implication
Overall returns	52.0% of order lines in the DMC dataset	Returns are a material unit-economics problem
Size bracketing	16.6% of line items; 73% returned; 23.5% of all returns	High-value pool for fit UX
Addressable bracket	40.5% of brackets keep exactly one size	Only this subset is clearly sizing-solvable
Size recommender	28.8% hit rate vs 19.1% item baseline	Personalization improves sizing decisions
Measured capture	2% of all returns; 6.9% theoretical ceiling	Avoid overpromising a 25% reduction

Why size/fit is the right MVP

The public evidence shows that a meaningful share of returns comes from customers ordering multiple sizes. A recommender can target the subset where one size is ultimately kept. Better garment measurements and review-derived signals should improve the recommendation and also identify SKUs whose published sizing is systematically off.

Impact — simple 1M-order scenario

Metric	Illustrative value
Order lines	1,000,000
Returns at 52% baseline	520,000
Avoided returns at 2% capture	10,400
Gross savings @ €3.60 / return	€37,440
Gross savings @ €5.14 / return	€53,456

Experiment plan

A/B test: control = current PDP; treatment = Fit Confidence.
Primary KPI: total and size/fit-related return rate. Guardrails: conversion, exchange rate, cancellation, AOV, customer satisfaction.
Segments: category, size, SKU, new vs repeat customer.
Decision: scale categories where return reduction outweighs intervention cost without harming conversion.

Source & caveat

Dataset: Kaggle, Predicting Returns of Discounted Articles Sales (Data Mining Cup 2016), ≈2.33M real order line items. The raw data is not redistributed here; the accompanying notebook downloads it at runtime. Sizing metrics and return-cost figures are from the public reproducibility analyses by myBytes Research. Myntra's internal data is not public, so these findings are directional rather than Myntra-specific
